and Research Institute of Oceanography,
Seoul National University
Characteristics of the Yellow and East China Sea

- Shallow and wide continental shelf, a steep continental shelf break
- Strong tides
- Seasonally variable winds
- Strong ocean current
- River discharge (Yangtze River et al.)

A bathymetry of the Yellow and East China Seas. Isobaths are in meters.
Previous Studies

- Seasonal variations of Yangtze River plume direction
  - by the wind and the Kuroshio Current (Hu, 1994)
  - by the fluctuation of River water, wind, bottom topography
    (Mao et al., 1963; Beardsley et al, 1985; Guan, 1994)

- Coastal density currents induced by buoyancy supply
  (Chao and Boicourt, 1986; Qui and Imasato, 1988)

- Stratified tidal rectification is an important process in the summertime subtidal flow in numerical model (Lee and Beardsley, 1999)

- Some numerical experiments considering wind variation, topography, and river discharge (Bang and Lee, 1999)
The surface salinity distributions off the Yangtze River mouth
(a) February, 1978, (b) June, 1975 (Hu, 1994)
Aim and Scope of the Present Study

In the former studies,

The circulation pattern of winter by wind effect in the YECS is relatively well known.

However, the circulation pattern of summer seems to be unclear. Especially the role of the tide is not clarified.

In the present study,

For the understanding of the circulation and the dispersion of the Yangtze River water, two major controlling factors, tide and wind effects, are systematically analyzed, and compared with observed data.
Numerical Model

Model configuration

Princeton Ocean Model (Blumberg and Mellor, 1987)
Horizontal Resolution : $1/6^\circ \times 1/6^\circ$, $117^\circ \sim 132^\circ$ E, $23^\circ \sim 42^\circ$ N
Vertical Resolution : 12 sigma levels
Time step : Internal mode 1863 seconds, External mode 48 seconds

➤ Characteristics of POM

• Free surface model
• Arakawa C grid
• Sigma grid system
• Mode splitting (external mode, internal mode)
• Turbulence closure sub-model : vertical eddy coefficients
Monthly variation of the mean discharge of the Yangtze River from January 1950 to December 1985 (from Shen et al., 1998).

A : $1.1 \pm 0.9$ Sv (Max. in Aug., min. in Feb.)
B : $23 \pm 0.35$ Sv (Max. in Sep., min. in Mar.)
C : $2.2 \pm 0.35$ Sv (Max. in Sep., min. in Mar.)
Y : monthly variation as above
D : $A + B + Y - C$
Heat Flux : monthly variations

The model domain and bathymetry in meters.
Input Data

Sea surface wind: Na and Seo (1998), 18-year (‘78~’95) monthly mean

- Tide: $M_2$ constituent, $\eta$ (elevation) and $U$ (current velocity) from Oh and Lee, 1998

- Temperature and Salinity: Levitus (1994), monthly mean

- Heat Flux: COADS data (1997), monthly mean

- Yangtze River discharge: 36-year averaged monthly mean (Shen et al., 1998)
## Experimental conditions

- **Applied forcing for prognostic calculation**

(YRD : Yangtze River Discharge)
Distributions of the sea surface (a) current, (b) salinity in Exp. 1 and (c) current, (b) salinity in Exp. 2 in August

- Exp. 1 (without tide)
  - The currents of the northern part of 32 deg. N. are suppressed.
  - The northward dispersion of the low salinity water is reduced.
  - The low salinity water converges the southeastern area off the Yangtze Bank.

- Exp. 2 (with tide)
  - The currents of the northern part of 32 deg. N. are suppressed.
  - The northward dispersion of the low salinity water is reduced.
  - The low salinity water converges the southeastern area off the Yangtze Bank.

When TIDE is included in August

Distributions of the sea surface (a) current, (b) salinity in Exp. 1 and (c) current, (b) salinity in Exp. 2 in August
The differences in surface salinity [psu] between those without tide and wind (Exp. 1) and with tide (Exp. 2) in August. Solid lines indicate the areas whose salinities are decreased by tidal effect.
TIDE effect in August

Exp. 1 (without tide)  Exp. 2 (with tide)

Vertical distributions of (a), (c) salinity, (b), (d) cross section current in Exp. 1, Exp. 2 respectively in August
When WIND is included in August

1. The eastward flows are somewhat intensified.

✓ The southward flows near southeastern area of the Yangtze River are much weakened.

wind stress : 0.007 N/m²

Distributions of the sea surface (a) current, (b) salinity in Exp. 1 and (c) current, (d) salinity in Exp. 3 in Aug.
The current of the northern part of 33 deg N are suppressed.

The low salinity water is directed southward and reaches the Taiwan Strait.

wind stress : 0.056 N/m²

Distributions of the sea surface (a)current, (b)salinity in Exp. 1 and (c)current, (d)salinity in Exp. 3 in Feb.
WIND effect in August and February

The differences in surface salinity [psu] between those without tide and wind (Exp. 1) and with wind (Exp. 3) in August and February. Solid lines indicate the areas whose salinities are decreased by wind effect.
The changes in the surface current on the box area (averaged below 30 psu) without tide and wind (dotted arrow) and addition of wind effect (solid arrow) in (a) August and (b) February.
When WIND + TIDE are included (Exp. 4)

Distributions of the sea surface (a),(c) current and (b),(d) salinity in Aug. and Feb. respectively in Exp. 4
Monthly variations of surface salinity in each Experiment.

The monthly variations of surface salinity (below 30 psu) in the box domain in case of wind and tide (Exp. 4), with tide only (Exp 2), and with wind only (Exp. 3).
Present Model Calculation (Exp. 4: TIDE+WIND)

Salinity from Drifter Survey

Surface Salinity [psu] August

(NFRDI)
Comparisons of model calculation and drifter experiments in July.
Red arrows : surface currents from the present model calculation
Black lines : trajectories of five drifers from 8th June to 9th July, 2003
(Matsuno, 2003).
Schematic diagram of the typical seasonal current system and dispersion of the Yangtze River’s low salinity water at sea surface.
Conclusions

1. Circulation of the Yellow and East China Seas;

   Winter : dependent on the very strong monsoon N, NE wind

   Summer : Tide is a dominant factor in the circulation near Yangtze river mouth,
            but the weakened S, SE wind still a considerable factor.
Conclusion

2. Dispersion of the Yangtze River water:
   General follows the circulation pattern fairly well

   Summer:
   - The tidal effect on the dispersion tends to spread southward and eastward by
     energetic vertical mixing processes.
   - The southerly wind effect tends to spread the low salinity water eastward.
   - Salinity of some northern area of the Yangtze River mouth increases more than
     10 psu as compared with the reference case.

   Winter:
   - The dispersion exactly follows the flow pattern southward along the east
     Chinese coast.
Thank You
